

## User Story 5.2: Data Quality Issue Flagging

**As a Sourcing Associate, I want spend records with data-quality issues (missing PO, missing supplier, broken relationship) flagged, so I don't act on unreliable numbers.**

### **Description:**

Surface a visible flag on spend records that have known data-quality issues - such as a missing PO, missing supplier link, or a broken relationship between related objects - so users can distinguish reliable records from ones that need caution.

### **Narrative:**

Not every spend record will cleanly link to all the objects it should (PO, supplier, contract, etc.), particularly during the phased rollout of Oracle AP, Coupa, and EAA curation. Rather than silently displaying incomplete or broken records the same way as clean ones, users need a clear signal when something is structurally off, so they can apply appropriate judgment before relying on that data.

### **Business Value:**

Prevents associates from making decisions - or building a business case - on top of structurally unreliable data. Reinforces overall trust in the tool by being transparent about known gaps rather than hiding them behind a clean-looking interface.

### **Acceptance Criteria:**

- Given a spend record is missing an expected PO reference, when displayed, then it is visibly flagged as having a data-quality issue
- Given a spend record is missing a supplier link, when displayed, then it is visibly flagged
- Given a relationship between two connected records (e.g. invoice to PO) is broken or unresolvable, when either record is displayed, then the broken relationship is flagged
- Given a user views a flagged record, when they investigate further, then the specific issue type (missing PO, missing supplier, broken relationship) is identified, not just a generic warning

### **Out of Scope:**

- Automatically resolving or correcting the underlying data-quality issue - this story covers flagging/visibility only, not remediation
- Categorization confidence flagging (covered separately in Epic 2, Story 2.2) - this story is about structural/relational data issues, not categorization uncertainty
